

Q1: Number Representation (10 points)

1) Convert the following 8-bit two's-complement numbers from hexadecimal to decimal:

0x80 = _____

0xFF = _____

0x0F = _____

2) For two n -bit numbers, what is the difference between the largest unsigned number and the largest two's-complement number? In other words, what is **MAX_UNSIGNED_INT** - **MAX_SIGNED_INT**? Write your answer in terms of n .

3) Fill in the blanks to return the largest positive number a 32-bit two's-complement number can represent.

```
unsigned int max_twos() {
    return ((1 << _____) - _____);
}
```

4) Consider a new type of notation for representing signed numbers, *biased* notation. The formula for obtaining the value from a number written in biased notation is:

$$\text{value} = \text{value_as_unsigned} - b$$

Where b is a constant called the *bias*. Example with 4 bits and a bias of 4:

$$\begin{aligned} 0b0011 &= 3 - 4 = -1 \\ 0b1110 &= 14 - 4 = 10 \end{aligned}$$

If we wanted an n -bit biased system to represent the same range as two's complement numbers, what is the value of b ?

Q2: Pointers and Memory (12 points)

1) Assume you are given an int array `arr`, with a pointer `p` to its beginning:

```
int arr[] = {0x61c, 0x5008, 0xd, 0x4, 0x3, 0x4ffc};
int *p = arr;
```

Suppose `arr` is at location `0x5000` in memory, i.e., the value of `p` if interpreted as an integer is `0x5000`. To visualize this scenario:

Assume that integers and pointers are both 32 bits. What are the values of the following expressions? If an expression may cause an error, write "Error" instead.

- a) `*(p+3) =`
- b) `p[4] =`
- c) `*(p+5) + p[3] =`
- d) `*(int*)(p[1]) =`
- e) `*(int*)(*(p+5)) =`

2) Consider the following code and its output. Fill in the blanks.

```
void foo1( _____ a, int n) {
    int i;
    for (i = 0 ; i < n ; i++) {
        (*(a+i)) += 3;
    }
}

void foo2( _____ p) { p++; }

int main() {
    int x = _____ ;
    int a[] = {1, 2, 3, 4, 5};
    int *p = &a[1];
    foo1(a, sizeof(a) / sizeof(int));
    foo2(&p);
    printf("%d, %d, %d\n", a[1], *(++p), a[x]);
}
```

The output of this code is:

_____, _____, 8

Q3: C Memory Model (6 points)

For each of the following functions, answer the questions below in the corresponding box to the right:

- 1) Does this function return a usable pointer to a string containing "asdf"?
- 2) Which area of memory does the returned pointer point to?
- 3) Does this function leak memory?

You may assume that `malloc` calls will always return a non-NULL pointer.

```
char * get_asdf_string_1() {
    char *a = "asdf";
    return a;
}
```

get_asdf_string_1
1)
2)
3)

```
char * get_asdf_string_2() {
    char a[5];
    a[0]='a';
    a[1]='s';
    a[2]='d';
    a[3]='f';
    a[4]='\0';
    return a;
}
```

get_asdf_string_2
1)
2)
3)

```
char * get_asdf_string_3() {
    char * a = malloc(sizeof(char) * 5);
    a = "asdf";
    return a;
}
```

get_asdf_string_3
1)
2)
3)

```
char * g = "asdf";

char * get_asdf_string_4() {
    return g;
}
```

get_asdf_string_4
1)
2)
3)

Q4: Linked Lists (12 points)**1) Fill out the declaration of a singly linked list node below.**

```
typedef struct node {
    int value;
    _____ next; // pointer to the next element
} sll_node;
```

2) Let's convert the linked list to an array. Fill in the missing code.

```
int * to_array(sll_node *sll, int size) {
    int i = 0;
    int *arr = _____;
    while (sll) {
        arr[i] = _____;
        sll = _____;
        _____;
    }
    return arr;
}
```

3) Finally, complete delete_even() that will delete every second element of the list. For example, given the lists below:Before: → → → After: → **Calling delete_even() on the list labeled "Before" will change it into the list labeled "After". All list nodes were created via dynamic memory allocation.**

```
void delete_even(sll_node *sll) {
    sll_node *temp;
    if (!sll || !sll->next) return;
    temp = _____;
    sll->next = _____;
    free(_____);
    delete_even(_____);
}
```

Q5: MIPS with FUNctions (18 points)

The function `countChars(char *str, char *target)` returns the number of times characters in `target` appear in `str`. For example:

```
countChars("abc abc abc", "a") = 3
countChars("abc abc abc", "ab") = 6
countChars("abc abc abc", "abcd") = 9
```

The C code for `countChars` is given to you in the box on right. The helper function `isCharInStr(char *target, char c)` returns 1 if `c` is present in `target` and 0 if not.

```
int countChars(char *str, char *target) {
    int count = 0;
    while (*str) {
        count += isCharInStr(target, *str);
        str++;
    }
    return count;
}
```

Finish the implement of `countChars` in TAL MIPS below. You may not need every blank.

`countChars`:

```
addiu $sp, $sp, _____
_____ # Store onto the stack if needed
_____
_____
```

```
addiu $s0, $zero, 0 # We'll store the count in $s0
addiu $s1, $a0, 0
addiu $s2, $a1, 0
```

loop:

```
addiu $a0, $s2, 0
_____
beq _____
jal isCharInStr
_____
_____
```

done:

```
_____ # Load from the stack if needed
_____
_____
_____
addiu $sp, $sp, _____
jr $ra
```

Q6: MIPS Instruction Formats (16 points)

Convert the following TAL MIPS instructions into their machine code representation (binary format) or vice versa. For rows where you convert instructions to machine code, we've provided boxes to the right that you should fill in with the appropriate fields (in binary):

<u>MIPS</u>	<u>Machine Code</u>						
foo_bar:	0b00000000100000000001000000100001						
loop: beq \$a1 \$0 end	<table border="1" style="width: 100%; height: 20px;"> <tr> <td style="width: 25%;"></td> <td style="width: 25%;"></td> <td style="width: 25%;"></td> <td style="width: 25%;"></td> </tr> </table>						
j loop	0b00001000000000000000000000000001						
end: jr \$ra	<table border="1" style="width: 100%; height: 20px;"> <tr> <td style="width: 16.6%;"></td> <td style="width: 16.6%;"></td> <td style="width: 16.6%;"></td> <td style="width: 16.6%;"></td> <td style="width: 16.6%;"></td> <td style="width: 16.6%;"></td> </tr> </table>						

Q7: MIPS Addressing Modes (16 points)

We have a function that, when given a branch instruction, returns the number of bytes that the Program Counter (PC) would change by, i.e. (**PC_of_branch_target - PC_of_branch_instruction**).

```
branchAmount(branch_inst):
    calculate the instruction offset from branch_inst
    convert the offset to byte addressing
    return PC_of_branch_target - PC_of_branch_instruction
```

Write branchAmount in TAL MIPS (no pseudoinstructions) .You may not need all the blanks. Assume that register \$a0 contains a valid branch instruction.

```
branchAmount:
    andi $t0, $a0, 0x8000      # Mask out a certain bit
    bne _____, _____, label1
    _____
    _____
    j label2
label1:
    _____
    _____
    or $v0, $a0, $t1
label2:
    sll _____, _____, _____ # Convert to byte addressing
    _____
label3:
    jr $ra
```
