CS 61C Midterm #2 — July 30th, 1998

Your name _____

login cs61c–_____

This exam is worth 30 points, or 15% of your total course grade. The exam contains six substantive questions, plus the following:

Question 0 (1 point): Fill out this front page correctly and put your name and login correctly at the top of each of the following pages.

This booklet contains seven numbered pages including the cover page, plus a copy of the back inside cover of Patterson & Henessey. Put all answers on these pages, please; don't hand in stray pieces of paper. This is a closed book exam, calucaltors are allowed.

When writing procedures, write straightforward code. Do not try to make your program slightly more efficient at the cost of making it impossible to read and understand.

When writing procedures, don't put in error checks. Assume that you will be given arguments of the correct type and specified format.

If you find one question especially difficult, leave it for later; start with the ones you find easier. We will use round to even as our rounding mode to round all fractional points to integer values.

Question 1, *Deja Vu* all over again (5 points):

1 point: Using two's complement, **saturating** arithmetic, add the following 8 bit numbers together.

```
      00110101
      00101111
    + 01011011
    ----------
```

1 point: Which IEEE rounding mode would you like us to use for dealing with fractional points, in order to maximize your score: round to $+\infty$, round to $-\infty$, truncate, or round to even?

1 point: Why does this not work as a translation of `li $rd` *imm*? *imm* is a 32 bit quantity, *high* is the upper 16 bits of *imm*, *low* is the lower 16 bits of `imm`:

```
    lui $rd high
    addiu $rd $rd low
```

1 point: What is the value of this 32 bit, two's complement number?

11111111 11111111 11111111 11110011?

1 point: What registers must be restored to their prexisting values when a function returns, according to the MIPS calling convention?

Question 2 (6 points):

Short questions on performance and I/O.

1 point: How many interrupts will be required to read 100 bytes of input, one byte at a time, using polling based I/O?

1 point: How many interrupts will be required to read 100 bytes of input, one byte at a time, using interrupt driven I/O?

1 point: How many interrupts will be required to read 100 bytes of input, using a DMA transfer?

1 point: Gill Bate's new operating system, Macro$haft WinBlows 00 requires 10 minutes to start up. 40% of this time is used to detect and remove non Macro$haft programs. If the Department of Justice forces the removal of this portion of the operating system, what is the best time the modified operating system (the version without the portion which detects non Macro$haft programs) requires to boot?

1 point: Inhell computer corporation claims that their new Multipersonality Extension (MPX instructions) based CPUs perform some operations, those represented by MPX instructions, up to 10 times faster, but all non MPX instructions are unaffected. Older programs do not use MPX instructions. What is the maximum percentage improvement which a MPX processor offers when running old programs?

1 point: A RISC machine has an average CPI of 1.5 and a clock rate of 500 MHz. How long will it take to execute a 100,000,000 instruction program?

Question 3 (6 points):

Short questions on boolean logic, circuits, computer components, etc.

1 points: Which of the following boolean expressions are true?

A or $0 = 0$, A or $0 = 1$, A and $\tilde{}A = 0$, A and $\tilde{}A = 1$

2 points: Give the truth table for the following boolean function and draw a circuit which implements it.

$O = AB$ or AC or $B\tilde{}C$

2 points: A state machine has 3 states, A, B, and C, and one input I. If the machine is in state A and I is true, it transitions to state B, otherwise it stays in state A. If the machine is in state B and I is true, it transitions to state C, otherwise it transitions to state A. If the machine is in state C it will always stay in state C. Draw the state transition diagram for this state machine

1 point: Which of the following tasks does the ALU perform: Store register value, perform arithmetic operations, perform comparisons, load data from memory?

Question 4 (6 points):

Consider this C program definition:

```
struct dispatchElement{
  char *name;
  int value;
  int (*fn)(int);
};

int opcode(int i);

int dispatch(struct dispatchElement *table, int operation){
  return ((table[opcode(operation)].fn)(operation));
}
```

Translate the function `dispatch` into MIPS assembly, using the register calling convention.
Hint:, draw the layout for a struct dispatchElement on the back side to make sure you fetch the correct fields of the structure.

```
        dispatch:
```

Question 5 (6 points):

Ben Bitdiddle has written the following faulty interrupt handler. The device in question can have interrupts enabled by writing a 1 to the address `0xffff0010`, and disabled by writing a 0 to that address. When this device generates an interrupt, the value `0xf00d` is placed in the cause register (coprocessor0 register $13). No other interrupt will generate this value for the cause register. He wants to allow other interrupts to proceed while his interrupt handler is processing this interrupt, but does not want to receive interrupts from the device in question. Only his interrupt handler manipulates the device's interrupt enable register, so he doesn't have to worry about someone else reenabling the device's interrupt. Unfortunately there are 3 bugs in his code. Identify each bug, correct it in the code, and explain why each bug is a problem. Code written out as ... is correct. He is allowed to use the stack for storage. His bugs **do not** invlove his enabling and disabling of interrupts or the manipulation of registers to enable or diable interrupts, but involve not correctly saving a register, enabling or disabling interrupts at the wrong time or in the wrong order, and using registers at inappropriate times. All comments correctly describe the behavior of the commented code.

```
    .ktext 0x80000080  # Forces interrupt routine below to
                       # be located at the right spot
intrp:
 1)    addi $sp $sp -20   # Get some stack space

 2)    mfc0 $k0 $13       # See what caused the interrupt
 3)    li $k1 0xf00d      # If it is not ours, skip on
 4)    bne $k0 $k1 other_interrupt

 5)    sw $t0 0($sp)      # Save $t0 and $t1
 6)    sw $t1 4($sp)

 7)    mfc0 $k0 $14
 8)    sw $k0 8($sp)      # Saving exception PC

 9)    mfc0 $k0 $12
10)    sw $k0 12($sp)     # saving status register
11)    ori $k0 $k0 1      # Set interrupt bit to 1 and relpace
12)    mtc0 $k0 $12       # which will reenable interrupts

13)    li $t0 0xffff0010  # Turn off the device
14)    li $t1 0           # so it doesn't send more
15)    sw $t1 0($t0)      # Interrupts
       # Continues on next page
```

```
        ...                  # The body of the code is correct

20)     lw $k0 12($sp)       # Load the status and
21)     mtc0 $k0 $12         # Disable interrupts

22)     li $t0 0xffff0010    # Reenable the device
23)     li $t1 1             # so it will send interrupts
24)     sw $t1 0($t0)

25)     lw $k0 8($sp)        # Restore registers
26)     lw $t0 0($sp)        # And return to $k0
27)     lw $t1 4($sp)

28)     rfe
29)     jr $k0

other_interrupt:         # This code is OK, and will
    ...                  # return on its own
```
